Abstract

In Tunisia, polychaete studies are very rare (Fauvel 1924 a, b; Westheide 1972; Zibrowius 1970, 1971; Cantone 1978; Ben Amor 1984; Zaâbi & Aflì 2005). The aim of this study was to update and fill in gaps in data of polychaetes of Tunisia. Samples were taken aboard the research vessel R/V *Hannibal* with a Van Veen grab (0.1 m²) and a core (0.009 m²). Nine sites located on the peninsula of Cap Bon on the NE coast of Tunisia, from Sidi Daoud to Ras Lahmer, were sampled in 2005 and 2006. A total of 5,920 individuals in 29 families and 88 species of polychaetes were identified. Twenty-nine species were newly recorded for Tunisia, including the ampharetid *Isolda pulchella* O.F. Müller, 1858 and the paraonid *Aricidea cerrutii* (Laubier, 1966). Diversity parameters were established. Abundance and species richness were higher in shallow waters dominated by *Protodorvillea kefersteini* (McIntosh, 1869) and *Malacoceros fuliginosus* (Claparède, 1868) than in deep waters where *Aponuphis fauveti* (Rioja, 1918) and *Euclymene palermitana* (Grube, 1840) dominated. Multivariate methods, including the Shannon diversity index, cluster analysis, and rank frequency analysis, were used to characterize the spatial structure and temporal variability of the different communities.

Key words: polychaetes, biodiversity, Tunisia, Mediterranean

Introduction

There have been very few polychaete studies in Tunisia, with the most important being Fauvel (1924 a–b), Zibrowius (1970, 1971), Westheide (1972), Cantone (1978) and Bouderesque (1997). Zghal & Ben Amor (1980) collected data on Tunisian polychaetes and listed 222 species. Later, Zghal & Azzouna (1982) added seven additional species. Subsequently, Zaâbi & Aflì (2005) studied the distribution of polychaetes along the northeastern coast of the Tunis Gulf. Several taxonomic and ecological works have been undertaken on other Tunisian macrobenthic fauna. Azzouz (1971) described the benthic fauna of north and southeast Tunisia; Ben Alaya (1972) studied the fauna associated with *Posidonia oceanica* in the Gulf of Tunis; Zaouali & Baeten (1985) studied the macrobenthic community in Bibans lagoon; Ben Mustapha et al. (2003) documented sponges from Tunisian coasts; Ayari & Aflì (2003) surveyed the macrobenthic fauna in Tunis Bay, and Mestiri et al. (2005) worked on ascidians collected from Zembra-Zembretta Island. However, there is an obvious lack of ecological studies of polychaetes. The objective of this paper is to characterize the

structure and distribution of the polychaete fauna on the eastern coast of Tunisia. This paper is part of the research framework MORGÉN (Modèle et Outils de Recherche sur les Gisements des Ecosystèmes coralligènes du Nord).

Materials and methods

Sampling and laboratory procedures. The study area at Sidi Daoud is situated in the NE Tunisian gulf and NW of Cap Bon, in a large bay with a width of 2 km and a depth of 1300 m (Fig. 1). It is an important bay between Ras el Fartas and Cap Bon. The Sidi Daoud area has a Mediterranean climate characterized by irregular precipitation with an average annual rainfall of 500 mm (Ben Salem 2000). The air temperature in Sidi Daoud's bay varies from 13 to 27°C (Ben Alaya 1972).

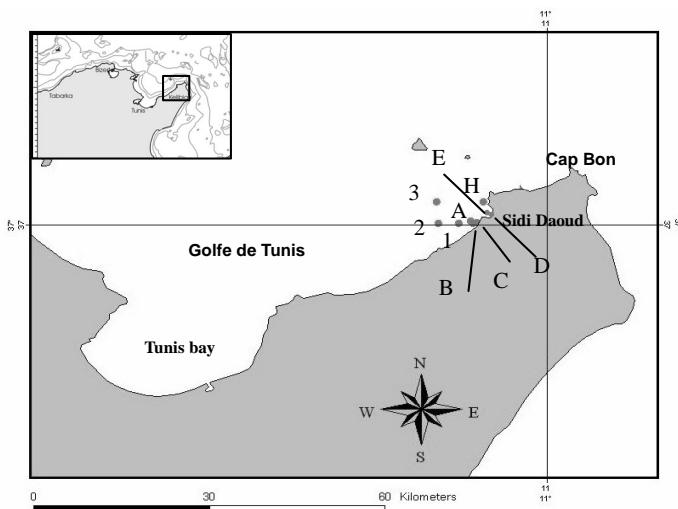

FIGURE 1. Map of the investigated area with location of the nine sampling sites from Sidi Daoud, Tunisia.

According to Lubet & Azzouz (1969), the bottom sediment type is influenced by geographical and hydrological conditions. The study site is a bay protected from the hydrodynamic conditions of the Mediterranean.

The polychaete fauna was sampled at nine sites (Fig. 1) during summer, autumn, and spring from 2005 to 2006. Station depths varied from 2–60 m (Table 1). Aboard the R/V *Hannibal*, a Van Veen grab (0.1m²) was used for the deep sites (1–3), and a cylindrical core for shallow sites (A–E and H). Samples were washed through a 1-mm-mesh sieve and fixed in 7% sea water formaldehyde for identification. In the laboratory, samples were rinsed in fresh water and preserved in 70% ethanol and the polychaetes were identified to species and counted. Polychaetes were identified using various guides, e.g., Fauvel (1923, 1927) and Fauchald (1977), and other papers for specific-level identification.

An additional sediment sample (100 g) was also taken at each site to measure particle grain size. These samples were dried for 48 h at 60°C, and then washed through a 63-µm-mesh sieve in order to separate the small (silt + clay) fraction (Afli & Chenier 2002). The remaining sediment was dried

again at 60°C, and all samples were then sieved through an AFNOR succession series of meshes (2000, 1400, 630, 500, 250, 180, 125, 100, and 63 μ m). The following granulometric fractions were observed: gravel (GR, >2 mm), very coarse sand (VCS, 2–1 mm), coarse sand (CS, 1–0.5 mm) medium sand (MS, 0.5–0.25 mm), fine sand (FS, 0.25–0.125), and silt + clay (>0.063 mm). Median grain size (Q_{50}) was determined for each sample and sediment types were characterized according to Chassé & Glémarec (1976). Sediments in the study area were exclusively sandy, ranging from coarse to fine sand (Table 1, Fig. 2).

TABLE 1. Coordinates and sediment type of nine sampling sites from Sidi Daoud, Tunisia.

Site	Position N	Position E	Depth (m)	Gravel (%)	Sand (%)	Silt (%)	Q_{50} (mm)	Sediment type
1	37°00'07"	10°50'04"	45	7.66	69.16	23.18	0.20	Fine sand

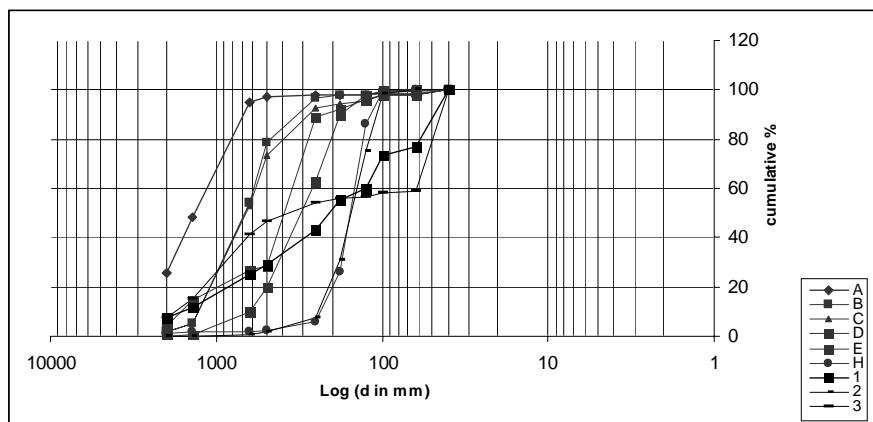

FIGURE 2. Cumulative curves for each sediment sample of the nine sites from Sidi Daoud, Tunisia.

Data analyses. An index was calculated for each sample for abundance of polychaetes (N), species richness (S), the Shannon-Weaver diversity index H' (\log_2) (Shannon & Weaver 1963) and Pielou's evenness J' (Pielou 1966). Rank-Frequency Diagrams (Frontier 1976) were proposed to study the community structure, based on two criteria: (1) the abundance of species and (2) the rank of species. RFD was originally applied to show temporal succession in a zooplankton community, but have since been used in spatio-temporal macrobenthic studies (Davout 1992).

The DIMO, DIversity MOdel proposed by Quinghong (1995) was used to represent species richness ($\log_2 S$), Pielou's evenness, and the Shannon-Weaver diversity index (H') in a two-

dimensional space. The faunal composition of shallow-water and deep-water sites in different seasons was compared using the Jaccard index and cluster analysis based on the similarity between stations in different seasons using the software PRIMER v6 (Clarke & Gorley 2005). A dendrogram was produced using Bray-Curtis similarity (Bray & Curtis 1957) and according to the following algorithm recommended by Lance & Williams (1967):

$$dh_{ij} = 0.625 dh_I + 0.625 dh_j - \beta dij \text{ (with } \alpha = 0.625 \text{ and } \beta = 0\text{).}$$

Results

Polychaetes collected in the peninsula of Cap Bon yielded a total of 5,920 individuals belonging to 88 species and 29 families (Appendix 1), of which 29 species (33 %) are new records for the Tunisian fauna. New records belong to four families, six genera, and 29 species. The new families are Paraonidae with six species [*Aricidea assimilis* (Tebble, 1959); *A. cerrutii* (Laubier, 1966); *A. fragilis mediterranea* Laubier & Ramos, 1974; *Paradoneis armata* Glémarec, 1966; *P. harpagonea* (Storck, 1967), and *P. lyra* (Southern, 1914)], Protodrilidae [*Protodrilus purpureus* (Schneider, 1868)], Saccocirridae (*Saccocirrus papillocercus* Bobretzky, 1871), and Paralacydoniidae (*Paralacydonia paradoxa* Fauvel, 1913). The new genera reported for Tunisia are *Armandia* (*A. polyphthalma* Küenthal, 1887); *Galathowenia* [*G. oculata* (Zaks, 1922)]; *Isolda* (*I. pulchella* F. Müller, 1858); *Metasynchis* [*M. gotoi* (Izuka, 1902)]; *Parathelepus* [*P. collaris* (Southern, 1914)]; *Parapionosyllis* [*P. gestans* (Pierantoni, 1903); *P. minuta* (Pierantoni, 1903) and *P. papillosa* (Pierantoni, 1903)], and *Polycirrus haematodes* (Claparède, 1864). Other species newly reported for Tunisia are *Aphelochaeta* cf. *marioni* (Saint-Joseph, 1894); *Caulieriella* cf. *alata* (Southern, 1914); *C. killariensis* (Southern, 1914); *Chaetozone* cf. *caputesocis* (Saint-Joseph, 1894); *C. gibber* (Woodham & Chamberlin, 1994); *Eunice schizobranchia* Claparède, 1870; *Glycera capitata* Oersted, 1843; *G. lapidum* Quatrefages, 1866; *Harmothoe lunulata* (Delle Chiaje, 1841); *Pista maculata* Marenzeller, 1884 and *Protodoryllea atlantica* (McIntosh, 1885). Genera represented by only one species are *Kefersteinia* *cirrata* (Keferstein, 1862), *Paralacydonia* *paradoxa* Fauvel, 1913; *Protodrilus* *purpureus* (Schneider, 1868); *Saccocirrus* *papillocercus* Bobretzky, 1871 and *Terebellides* cf. *stroemi* Sars, 1835.

The Dorvilleidae had the highest number of individuals in shallow water during autumn and spring, with 62% and 30%, respectively. In deep water, Maldanidae and Onuphidae were the most abundant in autumn with 17% and 15%, respectively, of the total abundance. In summer, the Onuphidae and Capitellidae were dominant with 21% and 17%, respectively, of the total abundance (Fig. 3).

The number of polychaete species per site in different seasons ranged from 1 (site E) to 22 (site H). The maximum abundance of polychaetes was found at site C in autumn and spring (Table 2), when the dorvilleid (*Protodoryllea kefersteini*) was dominant.

TABLE 2. Species richness (*S*) and abundance (*N*) for each sampling site in autumn (Au), spring (Sp), and summer (Su) for the polychaetes from Sidi Daoud, Tunisia.

Sites	1	2	3	A	B	C	D	E	H
N	60 (Su)	400	310 (Su)	40 (Sp)	120 (Sp)	950 (Sp)	550	10 (Sp)	520 (Sp)
	480 (Au)	(Su)	520 (Au)	140 (Au)	190 (Au)	1250 (Au)	(Sp)	10 (Au)	280 (Au)
		50 (Au)					40 (Au)		
S	4 (Su)	19 (Su)	14 (Su)	4 (Sp)	6 (Sp)	7 (Sp)	6 (Sp)	1 (Sp)	22 (Sp)
	22 (Au)	4 (Au)	18 (Au)	4 (Au)	7 (Au)	10 (Au)	2 (Au)	1 (Au)	17 (Au)

Two distinct groups of species are shown by cluster analysis with each having an average similarity higher than 50% (Fig. 4). The first group includes the all coastal sites in spring (*Csp*) and autumn (*Ca*), and the second group includes the deeper sites in summer (*Dsu*) and autumn (*Da*). The first group *Ca-Csp* is composed of three stations with a coarse sand bottom (A–C), two sites with medium sand (D–E) and one site with fine sand (H). This group is characterized by species such as *P. kefersteini* (1,030 m² in autumn) and *Malacoceros fuliginosus* (400 m² in spring). The second group consists of three deep sites with fine (sites 1–2) and medium sand (site 3). This group of sites had lower abundance and species richness (Table 3), and was characterized by *Aponuphis fauvelli* in summer and *Euclymene palermitana* in autumn.

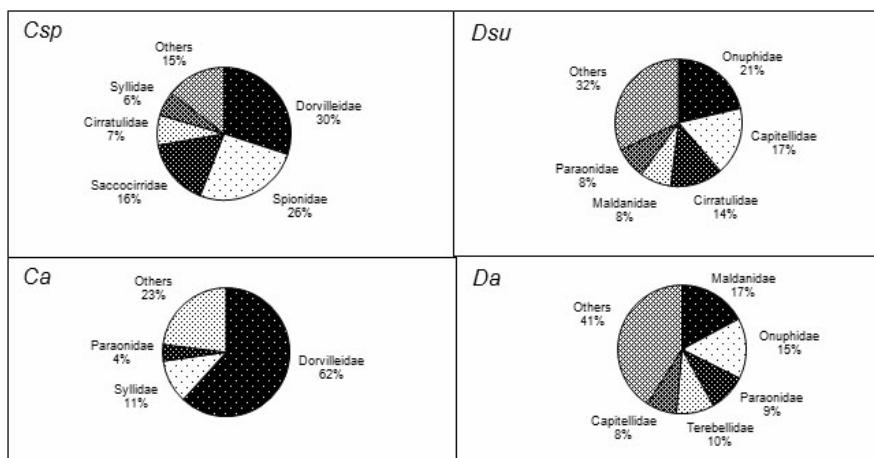

FIGURE 3. Polychaete family distribution from Sidi Daoud, Tunisia. *Csp*, coastal sites in spring; *Ca*, coastal sites in autumn; *Dsu*, deep-water sites in summer; *Da*, deep-water sites in autumn.

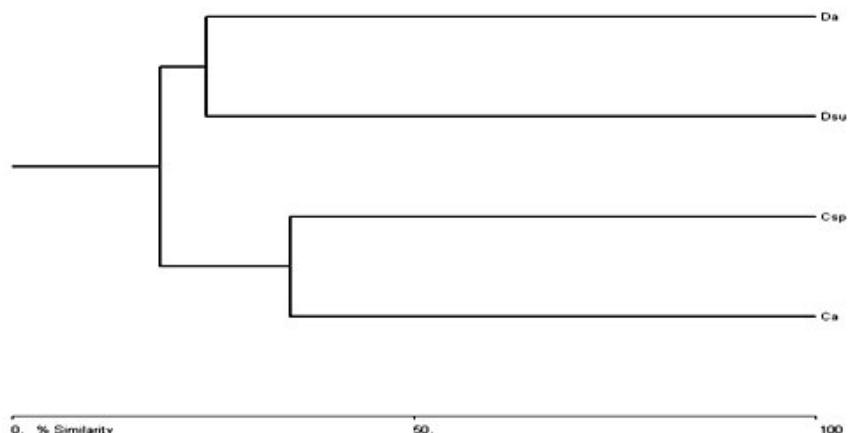

FIGURE 4. Result of the cluster analysis with the 88 species of polychaetes collected from Sidi Daoud, Tunisia. *Ca*, coastal sites in autumn; *Csp*, coastal sites in spring; *Da*, deeper sites in autumn; *Dsu*, deeper sites in summer.

The rank/frequency diagrams show the spatial and temporal differences between communities and represent a powerful tool to study community structure and its evolution toward successional stages (1, 2, and 3), defined by Rhoads & Germano (1982) as a transition from a stressed community with opportunistic species to a healthy community. The diagrams for the deep sites (Fig. 5A) from summer (*Dsu*) and autumn (*Da*) show a progressive straightening of the curves with a shift towards stage 3 corresponding to an equilibrium state (Frontier 1976) dominated by infaunal deposit-feeders. Some of these species are tubicolous (e.g., the polychaete family Maldanidae) but many others are mobile and free-living (Rhoads & Germano 1982).

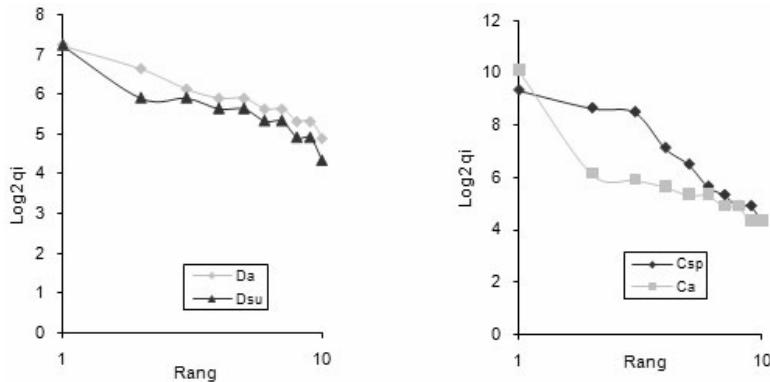

FIGURE 5. Rank/frequency diagrams for the polychaetes from Sidi Daoud, Tunisia. A, deep-water sites; B, shallow-water sites.

This change is marked by an increase in species richness and diversity ($H' = 3.53$ and $H' = 4.07$, Table 3). In shallow water sites (Fig. 5B), the community in autumn showed a stage 1 succession characterized by a pioneering community with the opportunistic *Protodorvillea kefersteini* as the dominant species (1,090 individuals) and the lowest value of the Shannon index ($H' = 2.61$, Table 3). In spring, the stage 1 continued with an increase in Shannon diversity ($H' = 3.05$) and proliferation of other opportunistic polychaetes such as *Malacoceros fuliginosus* and *Chaetozone gibber*. These small opportunistic polychaetes are among one of the first macrofaunal component to colonize a new or newly disturbed bottom (Rhoads & Germano 1982).

TABLE 3. Main characteristics of the polychaetes from Sidi Daoud, Tunisia. Abbreviations: Csp, coastal sites in spring; Ca, coastal sites in autumn; Dsu, deep-water sites in summer; Da, deep-water sites in autumn; S, Species richness; N, abundance; H', Shannon-Weaver diversity; J', Pielou's evenness.

Sites		Ca-Csp (A, B, C, D, E, H)		Da-Dsu (1, 2, 3)	
Season		Autumn	Spring	Autumn	Summer
Dominant species	<i>Protodorvillea kefersteini</i>		<i>Protodorvillea kefersteini</i>	<i>Euclymene palermitana</i>	
			<i>Malacoceros fuliginosus</i>	<i>Aponuphis fauvelli</i>	
			<i>Saccocirrus papilloccerus</i>	<i>Aricidea assimilis</i>	
			<i>Chaetozone gibber</i>		
S	36	36		34	27
N	1900	2190		1050	770
H'	2.61	3.05		4.07	3.53
J'	0.58	0.71		0.92	0.93

The DIMO model (Quinghong 1995) representing the three indices S, H', and J' (Fig. 6) confirms the results of cluster analysis and distinguishes two groups (*Ca-Csp* and *Da-Dsu*). This model illustrates the transition from the shallow coastal sites to the deeper sites which is accompanied by an increase of Shannon diversity and Pielou's evenness. In the sites belonging to the same group (coastal or deep sites), the seasonal variations were also marked by an increase in Shannon diversity and Pielou's evenness.

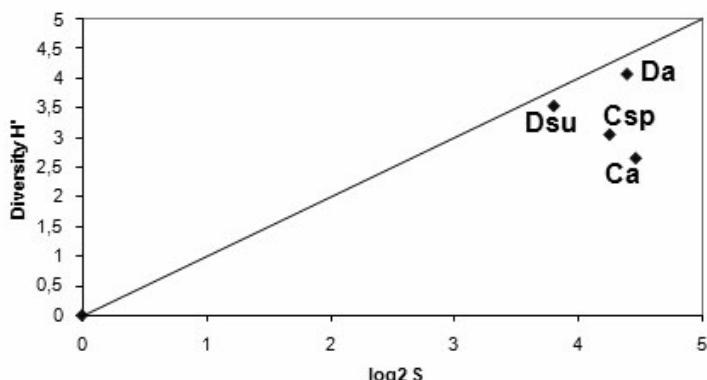

FIGURE 6. Position of different site groups according to the species richness and the diversity index H'; the diagonal line represent the maximum Pielou's evenness ($J' = 1$) for the polychaetes from Sidi Daoud, Tunisia.

Discussion

Comparison with polychaete fauna of Tunisia

Cantone (1978) reported 73 species of polychaetes in the Tunisian gulf in three different intertidal and infralittoral environments: *Posidonia* rhizomes, *Caulerpa*, and sandy shore. The species richness encountered in Sidi Daoud is similar to the results of Ayari & Afli (2003), who found 89 species of polychaetes in Tunis Bay. They defined three communities: (1) the heterogeneous sediments with higher species richness dominated by *Glycera convoluta* and *Lumbrineris fragilis*; (2) the muddy sediments characterized by a high abundance of *Melinna palmata*; and (3) the sandy sediments, limited to the harbor area of Rades, which was relatively poor faunistically and dominated by the capitellid *Notomastus latericeus*. Zaâbi & Afli (2005) studied the structure of polychaete assemblages along the northeastern coast of the Tunis Gulf. They listed 82 polychaetes species in three groups: (1) sandy and muddy sediments dominated by *Chaetozone cf. setosa* had the most species but the fewest individuals (58 species, 808 ind./m²); (2) the fine sand dominated by *Aricidea jeffreysii* and *Nephtys caeca* had fewer species but more individuals (45 species, 1833 ind./m²); and (3) the muddy sediments dominated by *Melinna palmata* had the fewest species and an intermediate number of individuals (19 species, 1240 ind./m²).

In the present paper, the distribution of polychaete families showed that tubicolous worms such as *Aponuphis fauveli* and *Euclymene palermitanus* dominated the deeper sites with sandy substrates; in shallow sites, opportunistic polychaetes like *Protodorvillea kefersteini* and *Malacoceros fuliginosus* were abundant. The fine substrate is favorable for the settlement of tubicolous polychaetes as the main constituent for tube building in agglomerated sand. This is the case for

carnivorous species that hide from predators in tubes such as the onuphid *A. fauveli*. Differences in species composition between the deep and shallow sites can be related to sediment characteristics, including their texture and organic matter content (Pérès 1961). Simboura et al. (2000) also considered the type of substrate and the hydrodynamics as major factors controlling polychaete distribution in shallow waters. Numerous other authors have also insisted on the importance of bathymetric factors (Bellan 1964; Baud & Bouteiller-Bougnol 1980).

The lowest values of species richness were found in shallow sites D–E in spring and autumn. These sites are situated in a small area of Sidi Daoud harbor in shallow water (Table 1) in front of an industrial discharge. The sediment is medium sand characterized by an abundance of gastropods shells and the absence of any type of vegetation. At the shallow sites, 70% of the total abundance was represented by four species: *P. kefersteini*, *M. fuliginosus*, *Saccocirrus papillocercus*, and *Chaetozone gibber*. We note the dominance of the opportunistic polychaete, *M. fuliginosus* (370 individuals in spring), which is considered an indicator of pollution (Bellan & Pérès 1970; Rebzani-Zahaf 1992). In spite of high species richness (Table 3), the shallow site group had the minimum values of Shannon diversity ($H' = 2.61$ in autumn and $H' = 3.05$ in spring, indicating moderate pollution ($3 < H' \leq 4$) according to Simboura & Zenetos (2002). The low diversity values at these sites testify to the dominance of a limited group of polychaete species with high abundance (Rebzani-Zahaf 1992). The Pielou's evenness threshold ($0.80 \geq J' > 0.65$) for macrobenthic communities according to Daget (1976) and Glémarec & Hily (1981), strengthen this conclusion. These results are similar to those found by Zaâbi & Afli (2006) for a disturbed site (IB2) in the Sidi Daoud area. This is probably due to organic enrichment resulting from industrial discharges (Ben Charrada 1997).

Comparison with polychaete fauna of Mediterranean Sea

The analysis of polychaetes of Sidi Daoud shows that the area is diverse with 88 species, of which 29 species (33 %) are new records for the coasts of Tunisia. Four families are new for the Tunisian coasts: Paralacydoniidae, Paraonidae, Protodrilidae, and Saccocirridae. The paraonids are already well known from the Mediterranean Sea (Laubier & Ramos 1973). The other new families (Paralacydoniidae, Protodrilidae, and Saccocirridae) were found in the Mediterranean Sea in Italy (Castelli et al. 1995), Spain (Moreira et al. 2006), and Algeria (Rebzani-Zahaf 1992), respectively. Some of the newly recorded species are common elsewhere in the Mediterranean Sea including species of *Metasynchis* Light, 1991; *Isolda* O.F. Müller, 1858, and *Parapionosyllis* Fauvel, 1923. The species *M. gotoi* (Izuka, 1902) has been found in Croatia (Gillet 1988), in Italy (Castelli et al. 1995), and in the Aegean Sea (Ergen et al. 2006). The absence of some species in previous studies could be due to the Lessepsian migrant status of some species such as *M. gotoi* (Ergen et al. 2006).

In a checklist of the Italian fauna the estimated number of polychaetes is 803 species (Castelli et al. 1995). In a study of collections from the Aegean Sea and a literature review, Arvanitidis (2000) estimated that 592 polychaete species were present. More recently, Dauvin et al. (2006) recorded 641 Mediterranean species on the French coast including 1,700 km along the Mediterranean Sea. Zghal & Ben Amor (1980) collected data concerning Tunisian polychaetes species and listed 222 species. The last inventory of polychaetes from the Tunisian coast was made by Ben Amor (1984) with 379 polychaete species. The present work adds 29 new species for a new total of 408 polychaete species from 1,300 km of the Tunisian coastline. The ratio of species (S) to coast length (C) is good for Tunisia, with a value of $S/C = 0.31$, which falls between the ratios for France (0.38) and Italy (0.11). The Tunisian coast is at the limit of the Western Mediterranean (884 polychaetes species) and the Central Mediterranean (528 polychaetes species) (Arvanitidis et al. 2002). The polychaete fauna of Tunisia includes 46% of the West Mediterranean species and 77% of the Central Mediterranean species.

Acknowledgments

This work is part of the research framework MORGÉN (Modèle et Outils de Recherche sur les Gisements des Ecosystèmes coralligènes du Nord). We are much indebted to the personnel of the R/V “HANNIBAL” and our colleagues Chaouch Mohamed and Othmen Afif for their help in sampling and treating benthic samples. We are also grateful to the anonymous reviewers for their reviewing, advising, and critical comments on the manuscript.

APPENDIX 1. List of species found in Sidi Daoud (northeast coast of Tunisia).

Species	Sampling Stations								
	1	2	3	A	B	C	D	E	H
<i>Amphicteis gunneri</i> (M. Sars, 1835)	x								
<i>Amphitritides gracilis</i> (Grube, 1860)	x								
<i>Aonides oxycephala</i> (Sars, 1862)								x	
<i>Aphelochaeta</i> cf. <i>marioni</i> (Saint-Joseph, 1894)	x	x	x						
<i>Aponuphis brementi</i> (Fauvel, 1870)								x	
<i>Aponuphis fauveti</i> (Rioja, 1918)	x	x	x			x			
<i>Arabella iricolor</i> (Montagu, 1804)								x	
<i>Aricidea assimilis</i> Tebble, 1959	x		x						
<i>Aricidea cerrutii</i> Laubier, 1966						x			x
<i>Aricidea fragilis</i> Webster, 1879	x	x	x						
<i>Armandia polyptalma</i> (Dujardin, 1839)					x	x			
<i>Brada villosa</i> (Rathke, 1843)								x	
<i>Caulieriella</i> cf. <i>alata</i> (Southern, 1914)			x						
<i>Caulieriella bioculata</i> (Keferstein, 1862)				x		x	x		
<i>Caulieriella killariensis</i> (Southern, 1914)	x								
<i>Chaetozone</i> cf. <i>caputesocis</i> (Saint-Joseph, 1894)			x					x	
<i>Chaetozone gibber</i> Woodham & Chamberlin, 1994	x							x	
<i>Chone duneri</i> Malmgren, 1867								x	
<i>Diopatra neapolitana</i> Delle Chiaje, 1841	x		x					x	
<i>Dodecaceria concharum</i> Örsted, 1843			x						
<i>Dorvillea atlantica</i> (McIntosh, 1885)						x		x	
<i>Drilonereis filum</i> (Claparède, 1870)			x						x
<i>Eteone longa</i> (Fabricius, 1780)					x				
<i>Euclymene palermitana</i> (Grube, 1840)	x		x						
<i>Eunice schizobranchia</i> Claparède, 1870	x								
<i>Eunice vittata</i> (Delle Chiaje, 1828)	x		x	x					
<i>Galathowenia oculata</i> (Zaks, 1922)	x								
<i>Glycera alba</i> (O. F. Müller, 1776)			x						
<i>Glycera capitata</i> Örsted, 1843		x							
<i>Glycera convoluta</i> Keferstein, 1862	x							x	
<i>Glycera lapidum</i> Quatrefages, 1866					x				
<i>Salvatoria limbata</i> (Claparède, 1868)				x					
<i>Malmgreniella lunulata</i> (Delle Chiaje, 1828)					x				x
<i>Harmothoe</i> sp. Kinberg, 1855			x		x				
<i>Hyalinoecia tubicola</i> (O. F. Müller, 1776)	x								
<i>Isolda pulchella</i> F. Müller, 1858			x						
<i>Kefersteinia cirrata</i> (Keferstein, 1862)				x	x				x
<i>Websterinereis glauca</i> (Claparède, 1870)				x					
<i>Lumbrineris fragilis</i> (O. F. Müller, 1776)	x

APPENDIX (continued)

Species	Sampling Stations							
	1	2	3	A	B	C	D	E
<i>Lumbrineris impatiens</i> (Claparède, 1868)	x	x		x				x
<i>Lumbrineris latreilli</i> Audouin and Milne-Edwards, 1834								x
<i>Lumbrineris paradoxa</i> Saint-Joseph, 1888				x				
<i>Lysidice ninetta</i> Audouin & Milne Edwards, 1833				x				
<i>Magelona rosea</i> Moore, 1907	x		x	x				
<i>Malacoceros fuliginosus</i> (Claparède, 1869)					x		x	x
<i>Maldane glebifex</i> Grube, 1860	x							
<i>Marphysa belli</i> Audouin & Milne-Edwards, 1833				x				
<i>Metasychis gotoi</i> (Izuka, 1902)	x							
<i>Naineris laevigata</i> (Grube, 1855)								x
<i>Nematonereis unicornis</i> Schmarda, 1861						x		x
<i>Nephtys caeca</i> (Fabricius, 1780)	x	x	x					
<i>Notomastus profundus</i> Eisig, 1887				x				
<i>Notomastus latericeus</i> M. Sars, 1851	x	x	x					x
<i>Ophelia limacina</i> (Rathke, 1843)								x
<i>Owenia fusiformis</i> Delle Chiaje, 1841			x					
<i>Paradoneis armata</i> Glemaréc, 1966		x				x		
<i>Paradoneis harpagonea</i> (Storch, 1967)					x			x
<i>Paradoneis lyra</i> (Southern, 1914)								x
<i>Paralacydonia paradoxa</i> Fauvel, 1913	x	x	x					
<i>Parapionosyllis gestans</i> (Pierantoni, 1903)					x			
<i>Parapionosyllis minuta</i> (Pierantoni, 1903)						x	x	
<i>Parapionosyllis papillosa</i> (Pierantoni, 1903)					x			
<i>Parathelepus collaris</i> (Southern, 1914)	x							
<i>Piromis eruca</i> (Claparède, 1870)		x	x					
<i>Pista cristata</i> (O. F. Müller, 1776)	x	x	x					
<i>Pista elongata</i> Moore, 1909			x					
<i>Platynereis dumerilii</i> (Audouin & Milne-Edwards, 1833)								x
<i>Polycirrus haematodes</i> (Claparède, 1864)				x				
<i>Polyptalmus pictus</i> (Dujardin, 1839)								x
<i>Prionospio cf. cirrifera</i> Wirén, 1883				x				
<i>Prionospio malmgreni</i> Claparède, 1869			x					
<i>Protodorvillea kefersteini</i> (McIntosh, 1869)			x		x	x	x	
<i>Protodrilus purpureus</i> (Schneider, 1868)					x			
<i>Pseudomalacoceros contabria</i> Rioja, 1919				x				
<i>Saccocirrus papillorcercus</i> Bobretzky, 1872						x		
<i>Scoloplos armiger</i> (O. F. Müller, 1776)	x	x						
<i>Sphaerosyllis capensis</i> Day, 1953				x				
<i>Sphaerosyllis hystrix</i> Claparède, 1863					x			

.....continued
