Abstract

A list of type depositories of new mite species published in two journals (*Systematic & Applied Acarology* and *Zootaxa*) during the last five years (2012–2016) is presented in this paper. The 1370 new species are deposited unevenly among 134 collections. The top collection is the Zoological Institute of the Russian Academy of Sciences, St. Petersburg, Russia (145 species), which alone accounts for 10% of the total new species, and the top ten collections accounted for 48% of the total. The average number of new species per collection is 10 and over three quarters of the collections are below the average. Just over half (51%) of the collections are in Europe. However, overall there were still more new species deposited in collections in developing countries (741) than developed countries (629). The top country for type depositories of new mite species for each continent is: Russia (199 species) for Europe, Brazil (134 species) for South America, Iran (133 species) for Asia, Australia (87 species) for Oceania, USA (80 species) for North America and South Africa (36 species) for Africa. The top European collections hold type specimens mostly of foreign origin, whereas those of South America, Asia, Africa and Australasia hold type specimens mostly originating from their own countries.

Key words: Acari, new species, type depository

Introduction

The primary type specimen(s) of a species are of great significance in nomenclature and taxonomy. The designation of a primary type—whether a holotype (or a series of syntypes) in the original descriptions of new species, or subsequent fixation of a lectotype from the type series, or a neotype in case of loss of the original primary type—provides an objective standard of reference for the application of the name it bears (International Commission on Zoological Nomenclature 1999; Art. 23). The value of name-bearing types lies in its function as standards of reference that provide objectivity in zoological nomenclature. If the concept of a new species is a hypothesis, then the future test of this hypothesis rests on the study of the primary type specimens. Therefore, they must be held in trust for science by the persons/institutions which serve as repositories for primary type specimens. Where are primary type specimens of mite new species deposited? The answer will of course depend on the time period as the trend may change over time. We are interested in the current situations. The main objective of this paper is to answer this question by conducting a survey of primary type depositories of new mite species described during the last five years (2012–2016). The second objective is to make this list of depositories available online for open access to ensure wide dissemination as recommended by International Commission on Zoological Nomenclature (1999).

Methods

To find the distribution of new mite species in various collections, we surveyed the type depositories of new species described in the last five years (2012–2016). We surveyed all papers with new species in two most important journals in mite taxonomy (*Systematic & Applied Acarology* and *Zootaxa*), which jointly accounted for about 38% of the total (Liu *et al.* 2013, p. 8 for comparison; Zhang 2017, p. 895 for the recent rise of *Systematic &*

Applied Acarology as the largest journal in acarology). Our methods generally follow those used in previous surveys of hotspots of new mite species (Liu *et al.* 2013; Liu & Zhang 2016; Lam & Zhang 2016; Li & Zhang 2016).

Results and discussion

Number of new species and type depositories

Our survey revealed that 1370 new species were reported in *SAA* and *Zootaxa* during the last five years (2012–2016). Liu *et al.* (2013, p. 8) reported 1130 new species during the five years from 2007 to 2011. Thus the last five years saw a 21% increase over the previous five-year period (2007 to 2011), which is probably due to the rapid increase in the volume of *SAA* in recent years (Zhang 2015, 2016, 2017).

The 1370 new species of Acari described in *SAA* and *Zootaxa* during 2012–2016 were deposited in 134 collections around the world (Table 1). The distribution of these new species among the collections is highly uneven. The top collection is the Zoological Institute of the Russian Academy of Sciences, St. Petersburg, Russia (145 species), which alone accounted for just over 10% of the total. The top ten collections (no. 10 is tied by the Australian National Insect Collection and Ohio State University Acarology Collection; so there are 11 collections among the “top 10”) combined accounted for 50% of the total. The average number of new species deposited per collection is 10 and over three quarters of the collections are below the average. Many collections have few new species deposited; e.g. 48% of the collections only had 1–3 new species each.

Note: Ma *et al.* (2016) failed to indicate the repository of the holotype of *Typhlodromus (Anthoseius) shanxi* Ma & Fan, 2016.

Ma worked at the Insect Ecology Laboratory, College of Agronomy, Shanxi Agricultural University, Taigu, China, where the specimens are deposited (confirmation through correspondence with the authors).

The 134 collections are distributed unevenly in 45 countries, with just over half (23) in Europe where natural history museums and other institutions are concentrated for historical reasons (Table 2). Not surprisingly, among the top 10 collections, the top three are located in Europe: ZISP of Russia, RMNH of the Netherlands and AMU of Poland (Table 1). Only four of the top 10 collections are located in developing countries: NJAU of China, ESALQ-USP and PEU of Brazil and BASU of Iran (Table 1 and Table 2). However, overall there were still more new species deposited in collections in developing countries (741) than developed countries (629) (Table 2). The top country for each continent is Russia (199 species) for Europe, Brazil (134 species) for South America, Iran (133 species) for Asia, Australia (87 species) for Oceania, USA (80 species) for North America and South Africa (36 species) for Africa (Table 2).

Previous surveys of hot spots of new mite species discovery (Lam & Zhang 2016, Li & Zhang 2016, Liu & Zhang 2016) show that many developing countries top the list for new species of mites (Table 3). The disparity of the two distributions (repository in Table 2 versus origin in Table 3) is due to most European collections holding primary type specimens of foreign origin (Table 4): 69.3% for Russia, 100% for The Netherlands and 97.7% for Poland. This is alarming in that some of these museums or collections do not loan specimens to international researchers either due to their policy or the lack of funds to manage the loan programme or for postage. It is very

expensive for overseas researchers from outside Europe to visit museums in Europe. Thus it is important that researchers deposit primary type specimens in institutions in the countries of origin. Indeed, some countries such as Brazil, now have laws on this requirement. The top developing countries in Asia, Africa and South America, however, show a different pattern from that of their European counterparts: most of their type specimens originated from their own countries, ranging from 97.7% for Iran to 86.1% for South Africa (Table 4). New Zealand and Australia, although considered developed countries, also have most of the type specimens from their own countries (100% and 82.8% respectively), whereas USA has nearly half of their holdings originating from its own countries (47.4%). When there are multiple specimens, some systematists spread the risk of loss by depositing specimens of the type series in collections in different countries, including the country of origin. This strategy is to be encouraged as it can also facilitate access to these specimens.
